# Lab 8: PCA Mini Project

Trevor Hoang (PID: A16371830)

Today we will do a complete analysis of some breast cancer biopsy data but first let's revist the main PCA function in R pccomp() and see what scale=TRUE/FALSE does.

#### head(mtcars)

                                                   0.5346787
                                                                0.9784574
     qsec
                    ٧s
                                            gear
                                                        carb
1.7869432
            0.5040161
                         0.4989909
                                      0.7378041
                                                   1.6152000
```

It is clear that "disp" and "hp" have the highest mean values and the highest sd here. They will likely dominate any anylysis I do on this dataset. Let's see

```
pc.noscale = prcomp(mtcars, scale=F)
pca.scale = prcomp(mtcars, scale=T)
```

### biplot(pc.noscale)

#### pc.noscale\$rotation[,1]

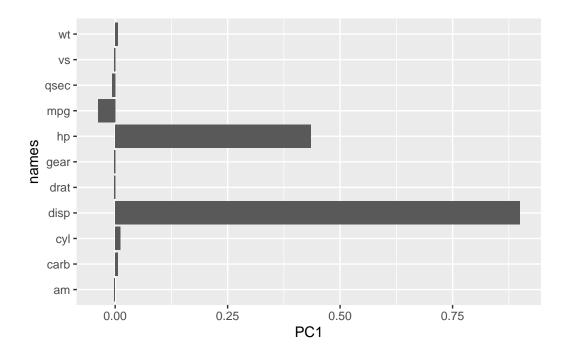

```
mpg cyl disp hp drat wt
-0.038118199 0.012035150 0.899568146 0.434784387 -0.002660077 0.006239405
    qsec vs am gear carb
-0.006671270 -0.002729474 -0.001962644 -0.002604768 0.005766010
```

Plot the loadings

```
library(ggplot2)

r1 = as.data.frame(pc.noscale$rotation)
r1$names = rownames(pc.noscale$rotation)
```

```
ggplot(r1)+
aes(PC1, names) +
geom_col()
```

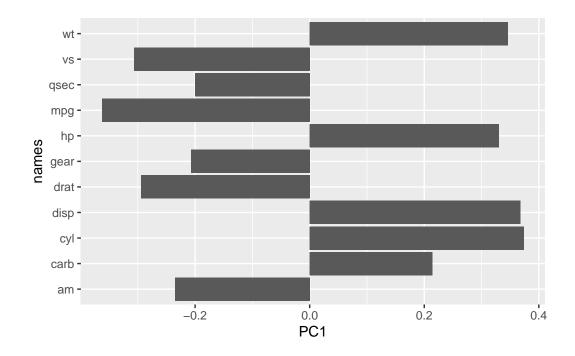

```
library(ggplot2)

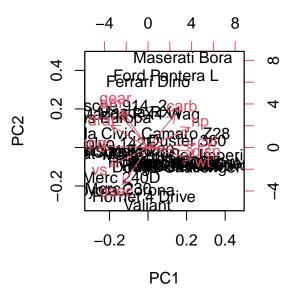

r2 = as.data.frame(pca.scale$rotation)

r2$names = rownames(pca.scale$rotation)

ggplot(r2)+
  aes(PC1, names) +
  geom_col()
```

biplot(pca.scale)

Take-home: Generally we always want to set scale=TRUEwhen we do this type of analysis to

avoid our analysis being dominated by individual variables with the largest variance just due to their unit of measurement.

## #FNA Breast Cancer data

Load the data into R.

```
wisc.df = read.csv("WisconsinCancer.csv", row.names=1)
head(wisc.df)
```

Q1. How many observations are in this dataset?

# nrow(wisc.df)

[1] 569

Q2. How many of the observations have a malignant diagnosis?

```
sum(wisc.df$diagnosis=="M")
```

[1] 212

The table() function is super useful here

```
table(wisc.df$diagnosis)
```

```
B M
357 212
```

Q3. How many variables/features in the data are suffixed with \_mean?

```
ncol(wisc.df)
```

#### [1] 31

#### colnames(wisc.df)

```
[1] "diagnosis"
                                "radius_mean"
 [3] "texture_mean"
                                "perimeter_mean"
 [5] "area_mean"
                                "smoothness_mean"
 [7] "compactness_mean"
                                "concavity_mean"

                                "symmetry_worst"
[31] "fractal_dimension_worst"
```

A useful function for this is grep()

```
length(grep("_mean", colnames(wisc.df)))
```

#### [1] 10

Before we go any further we need to exclude the diagnosis column from any future analysis this tells us whether a sample to cancer or non-cancer.

```
diagnosis = as.factor(wisc.df$diagnosis)
head(diagnosis)
```

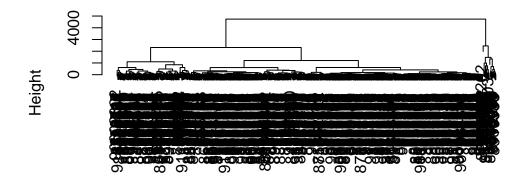

[1] M M M M M M M Levels: B M

```
wisc.data=wisc.df[,-1]
```

Let's see of we can cluster the wisc.data to find some structure in the dataset.

```
hc = hclust(dist(wisc.data))
plot(hc)
```

# **Cluster Dendrogram**

dist(wisc.data) hclust (\*, "complete")

# Principal Component Anaylsis (PCA)

```
wisc.pr = prcomp(wisc.data, scale=T)
summary(wisc.pr)
```

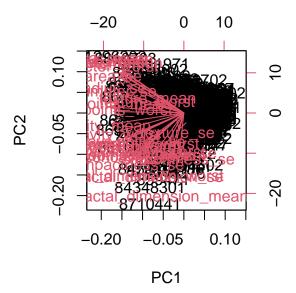

Importance of components:

```

- Q4. From your results, what proportion of the original variance is captured by the first principal components (PC1)? PC1 has 44.27% of the original variance
- Q5. How many principal components (PCs) are required to describe at least 70% of the original variance in the data? You need 3 PCs to describe at least 70% of the original variance.
- Q6. How many principal components (PCs) are required to describe at least 90% of the original variance in the data? You need 7 PCs to describe at least 90% of the original variance.

#### biplot(wisc.pr)

Q7. What stands out to you about this plot? Is it easy or difficult to understand? Why? It is really difficult to understand because all of the subject numbers are stacked on top of one another.

This biplot sucks! We need to build our own PCA score plot of PCI vs PC2

843786
         0.0007296587 -0.019703996 -0.0034564331
```

Plot of PC1 vs PC2 the first 2 columns

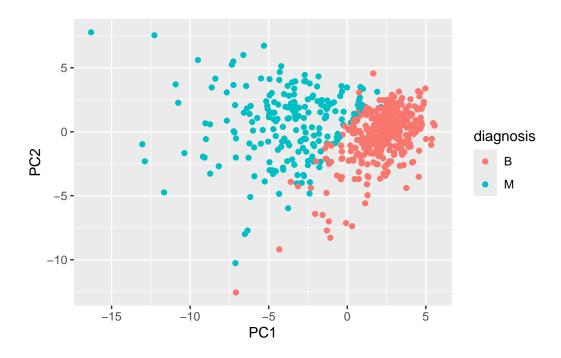

```
plot(wisc.pr$x[,1], wisc.pr$x[,2], col=diagnosis)
```

Make a ggplot version of this score plot

```
pc2 = as.data.frame(wisc.pr$x)

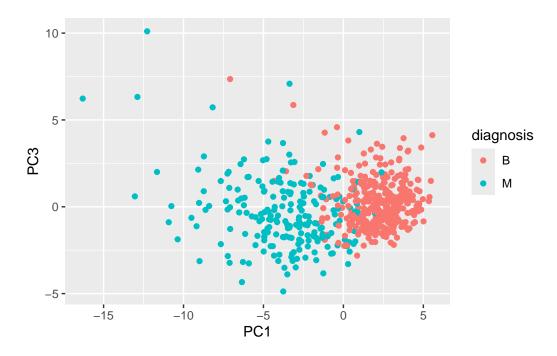

ggplot(pc2) +
  aes(PC1, PC2, col=diagnosis) +
  geom_point()
```

Q8. Generate a similar plot for principal components 1 and 3. What do you notice about these plots?

```
pc = as.data.frame(wisc.pr$x)

ggplot(pc) +
  aes(PC1, PC3, col=diagnosis) +
  geom_point()
```

These plots have very similar clustering meaning that the benign and malignant tumors most likely have very similar data However PC3 seems to have less variance.

#### **Variance**

Trying to find a hint as to which natural number it may be.

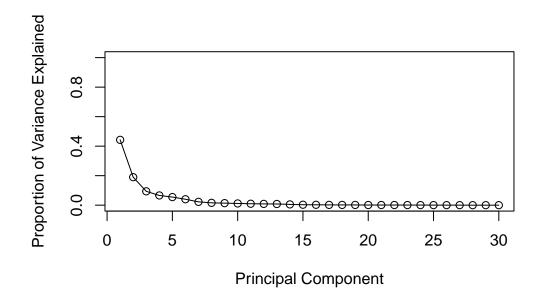

```
pr.var = wisc.pr$sdev^2
head(pr.var)
```

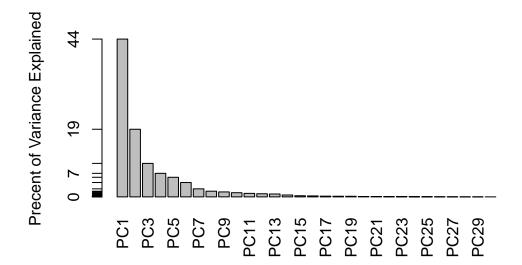

```
[1] 13.281608 5.691355 2.817949 1.980640 1.648731 1.207357
```

Finding the variance explained by each principal component

```
pve = pr.var/sum(pr.var)

plot(pve, xlab = "Principal Component",
    ylab = "Proportion of Variance Explained",
    ylim = c(0, 1), type = "o")
```

Q9. For the first principal component, what is the component of the loading vector (i.e. wisc.pr\$rotation[,1]) for the feature concave.points\_mean?

```
wisc.pr$rotation["concave.points_mean",1]
```

[1] -0.2608538

The component of the loading vector for concave.points\_mean is -0.26085376

Q10. What is the minimum number of principal components required to explain 80% of the variance of the data? You need 5 PCs to explain 80% of the variance of the data.

##Hierarchical Clustering

Scaling the data

```
data.scaled = scale(wisc.data)

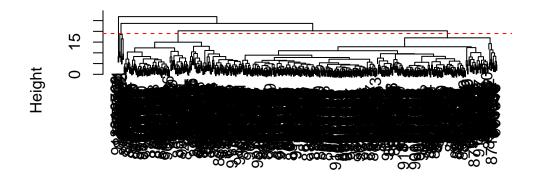

data.dist = dist(data.scaled)

wisc.hclust = hclust(data.dist, method="complete")
```

Q11. Using the plot() and abline() functions, what is the height at which the clustering model has 4 clusters?

```
plot(wisc.hclust)
abline(h=19, col="red", lty=2)
```

# **Cluster Dendrogram**

# data.dist hclust (\*, "complete")

There are 4 clusters at 19.

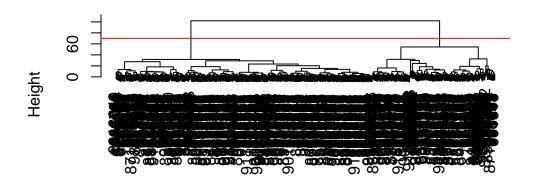

Cutting the tree

```
wisc.hclust.cluster = cutree(wisc.hclust, h=19)
table(wisc.hclust.cluster, diagnosis)
```

- Q12. Can you find a better cluster vs diagnoses match by cutting into a different number of clusters between 2 and 10? No, if we cut into 2 or 10 clusters, we will end up with false negatives and false positives.
- Q13. Which method gives your favorite results for the same data.dist dataset? Explain your reasoning.

```
wisc.pr.hclust = hclust(data.dist, method="ward.D2")
plot(wisc.pr.hclust)
abline(h=70, col="red")
```

# **Cluster Dendrogram**

# data.dist hclust (\*, "ward.D2")

"ward.D2" is my favorite due to the fact that it is the least condensed an the easiest to look at.

##Cluster membership vector

```
grps = cutree(wisc.pr.hclust,k=2)
table(grps)
```

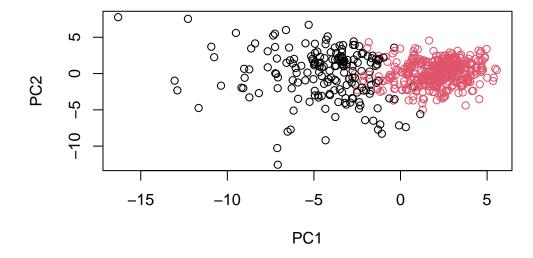

```
grps
1 2
184 385
```

Cross-table to see how my clustering groups correspond to the expert diagnosis vector of M and B values.

```
table(grps, diagnosis)
```

```
diagnosis
grps B M
1 20 164
2 337 48
```

```
plot(wisc.pr$x[,1:2], col=grps)
```

Q15. How well does the newly created model with four clusters separate out the two diagnoses?

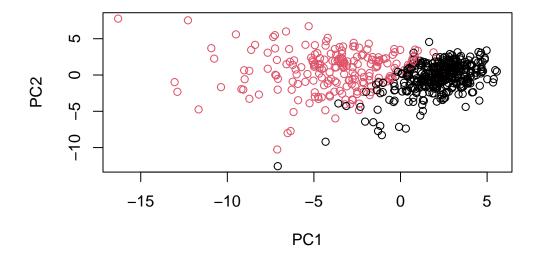

Positive = cancer M Negative = non-cancer B

True = cluster/grp 1 False grp 2

True Positive = 164 False Positive = 20 True Negative = 337 False Negative = 48

Q16. How well do the k-means and hierarchical clustering models you created in previous sections (i.e. before PCA) do in terms of separating the diagnoses? Again, use the table() function to compare the output of each model (wisc.km\$cluster and wisc.hclust.clusters) with the vector containing the actual diagnoses. The models used seperate the diagnoses pretty well, but they are still a little bit inaccurate.

```
plot(wisc.pr$x[,1:2], col=diagnosis)
```

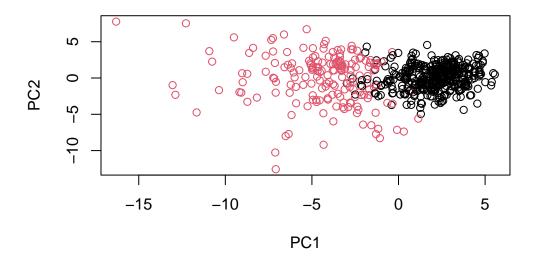

```
g = as.factor(grps)
levels(g)
```

[1] "1" "2"

g = relevel (g,2)
levels(g)

[1] "2" "1"

plot(wisc.pr\$x[,1:2], col=g)

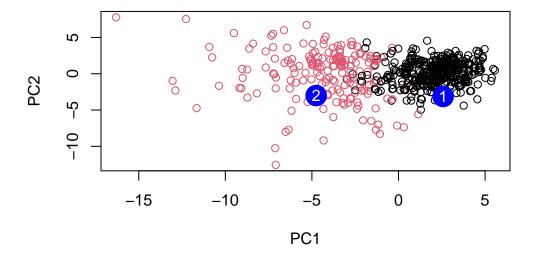

We can use our PCA results (wisc.pr) to make predictions on new unseen data.

```
#url <- "new_samples.csv"
url <- "https://tinyurl.com/new-samples-CSV"
new <- read.csv(url)
npc <- predict(wisc.pr, newdata=new)
npc</pre>
```

```
